PREFACE

This is the Final Report on studies related to Ka-Band System Reliability Improvement under Air Force Contract No. F33615-75-C-1208. The report is organized in three parts. Part I, Volume I, depicts the system model as organized in its functional relationship form; describes the overall program; presents the probabilistic estimates of reliability, maintainability, availability, dependability, etc. of the Ka-Band SATCOM Set based on all the data available; identifies the components most likely to malfunction or fail; and presents guidelines for the specification of reliability and maintainability requirements for the next generation system. Part I, Volume II, contains Appendix B which presents detailed results of the Tabular System Analysis (TASA) of the Ka-Band SATCOM Set. Part I, Volume III contains Appendix C which presents detailed results of the numerical reliability, availability and dependability predictions for the Ka-Band SATCOM Set. Part II contains guidelines for an Integrated Reliability and Maintainability (R/M) Program Plan intended as a model for the specific R/M plans that will be required for the procurement of future generation systems. Part III is the DEPEND Computer Program User's Manual. The DEPEND (Determination of Equipment Performance and Expected Nonoperational Delay) program is used to perform the arithmetic and documentation for the Tabular System Analysis.

APPENDIX C
RESULTS OF ANALYSIS OF THE
KA-BAND SATCOM SET

1 01 02 04 4

SECTION I
RESULTS OF ANALYSIS OF THE
KA-BAND SATCOM SET

INTRODUCTION

In the following pages computer print-outs are given detailing the results of the analyses of the Ka-Band SATCOM Set*. As noted in the Review and Comment section of this report**, three analyses were performed: the flight test data analysis, the theoretical analysis, and a combined analysis (A Bayesian combination of theoretical and flight test data).

The first computer print-outs present a summary of the results of the combined analysis for some of the more important functional sub-assemblies of the ADM Ka-Band SATCOM Set. Following these computer-generated summaries is a complete listing of all the results, at all functional levels, of the combined analysis of the Ka-Band Set. Following this, abbreviated partial results of the flight test data analysis and of the theoretical analysis are given, including results for only the major functional assemblies. Thus the reader is presented with a complete detailed print-out of the analysis which, in Battelle's opinion, yielded the best results, and is also given partial results of the other analyses so that differences between them, and techniques for combining the data may be studied.

The major part of this appendix is data or information in the form of computer printouts. The appendix is organized in the three following sections.

SECTION II. Analysis of the Ka-Band SATCOM Set based on the combined data, including:

- A. Input data tabulation
- B. Analysis schedule
- C. Summary of results
- D. Analysis summary

SECTION III. Abbreviated results of analysis based on flight test data, including:

- A. Input data tabulation

*Analyses of UHF equipment is not included.
**The Review and Comment Section is contained in Volume I.

B. Summary of results

C. Analysis summary for selected functional assemblies

SECTION IV. Abbreviated results of analysis based on theoretical data, including:

A. Input data tabulation

B. Summary of results

C. Analysis summary for selected functional assemblies

DATA COMBINATION

In performing analyses of the Ka-Band set, the set was first broken down into "black boxes" or basic functional building blocks consisting of modules, chassis, drawers, etc. This breakdown was accomplished with the help of the equipment manufacturers. The equipment manufacturers also provided reliability estimates for each of these basic functional building blocks, obtained using the methods of MIL-Hdbk-217-B. Estimates of the reliabilities of these various functional basic building blocks were also obtained through study and analysis of data taken during the flight test program for the ADM Ka-Band SATCOM set. As noted in the main body of this report, each of these sets of data provide information not contained in the other set. Thus, in Battelle's opinion, a combination of the two sets of data provides the best available estimate of the reliabilities of the basic functional building blocks. As the reliabilities of these blocks are rolled up in the course of the analysis into the reliability of the larger functional building blocks, and of the Ka-Band SATCOM set, a combination of the data provides the best reliability estimates at all functional levels. Bayesian statistics provide a method for combining data so that an original estimate of reliability can be made and then be improved as subsequent data becomes available. A discussion of the various ramifications of Bayesian statistics is beyond the scope of this report, but a brief description of the manner in which the data were combined is pertinent.

The methods of MIL-Hdbk-217-B depend on failure-rate data for parts obtained from experience and testing of these parts. In order to combine the theoretical data and the flight test data, it was necessary to

estimate the number of test hours represented by the figures used in MIL-Hdbk-217-B predictions. Based on Battelle's extensive experience in reliability, it was felt reasonable to assume that the failure rate data given in MIL-Hdbk-217-B, on the average, represented results of about ten 1,000-hour experiments or 10,000 test hours. For each of the functional building blocks the methods of MIL-Hdbk-217-B provided an estimate or prediction of the MTBF of that block. The 10,000 hours assumed test time was divided by this MTBF in order to estimate the average number of failures that would have occurred in the 10,000 hours. This procedure then provided an estimate of the number of test hours and the average number of failures that would have occurred during these hours if the tests had actually been conducted in the manner hypothesized.

From the flight test data it was possible to determine an actual number of hours of operation of the equipment, and the actual number of failures that occurred during this period*. The information was studied in order to cull from it shut-downs which were not properly attributable to failure of the equipment, such as shut-downs to make changes or modifications in the equipment, etc. Also censored were failures due to wear and because of the considerable amount of maintenance, excessive pattern failures, and conditions which were eliminated by equipment modification. When this task had been completed, data were available from the flight test providing the number of hours of test and the number of failures that occurred during these flight test hours for each of the basic functional building blocks.

To combine these two sets of data the 10,000 hours of assumed test time were added to the flight test hours which (including the roof top equipment operating time) was about 3400 to 3900 hours. The numbers of failures of any basic functional building block experienced during the flight test hours in both the aircraft and rooftop equipment were added to the number of failures calculated from the MIL-Hdbk-217-B reliability estimates as described above. In this way combined figures for a total number of test hours and a total number of failures were obtained. These figures then served as the basis for the combined reliability analysis. The results can be expressed as an MTBF

*Only the data for the calendar period from October, 1976, to October, 1977 were utilized because data prior to this interval are incomplete and include a significant amount of equipment debugging.

representing an average estimated use of the various functional blocks during a typical mission. In combining the data, if no failures were observed during the flight test, zero failures were added to the failures predicted by the methods of MIL-Hdbk-217-B.

INITIALIZATION

In starting up the equipment there is an initialization procedure that must be followed. For the purposes of the analyses in this report it has been assumed that this initialization procedure requires six minutes. This is based on the fact that there is a five-minute period during which information stored on punched paper tape is loaded into the system, and one minute has been allowed for system adjustments. The analyses consider that such initialization occurs only once during a mission. If there is a failure so that the system is shut down, there may be a need for an additional initialization procedure after repairs have been made. This is covered in the analysis by including the additional necessary initialization time in the mean restoration time for the equipment.

COMPUTATIONS

The availability, dependability, reliability, and maintainability estimates for this report were accomplished using the TASRA (tabulated system reliability analysis) approach. (Part I, Volume I, Appendix A provides a description of the TASRA computations.) The maintainability estimates are based on an overlap factor of 0.8; that is, it is assumed that in the case of more than one malfunction, the time to restore is the maximum of the individual restore time plus 80 percent of the sum of the other restore times.

PRESENTATION FORMATS

The formats used for presenting the analysis results are described in the following paragraphs.

Input Data Tabulation

The input data tabulation lists the ELEMENT LABEL, which is an identification number for each element followed by a listing of the DATA IDENTIFICATION, which describes each data element. The elements include

functional blocks of the system and the various possible states of malfunction or failure of these blocks, as used in the analyses. The functional blocks can be readily identified because the element label number associated with these blocks has a zero following the decimal point. Thus element label 115.0 is the teletypewriter. The various malfunction states for the teletypewriter are then listed under element label 115, but with various numbers following the decimal point. Element label number 115.1, for example, and its associated data identification (NO/INCORRECT TTY TRANSMISSION AND RECEPTION) provide the information that the teletypewriter has a state in which it is not operational in that both the transmission and reception are incorrect or are not functioning at all.

The column headed CYCLES contains a 1 or a 0, indicating that the functional block listed is or is not used during the mission for which the specific analysis is being performed.

The column headed USE, SECONDS, lists the number of seconds required to complete one functional cycle of the subject functional block. Thus element 4.0, the SATCOM Terminal Primary Power, for example, is used for 36,000 seconds; that is, for the entire ten hours of the mission described in the main body of this report. The functional cycle duration for most functional blocks is 4.2 seconds, although there are several exceptions.

The column labelled MTBF, HRS, lists the MTBF associated with that assembly or malfunction, in hours. (It should be remembered that these figures constitute an input to the computer program.) This column, and the last column, MTTR, HRS, at the basic building block level, contain data generated during flight test, received from manufacturers, etc. The results obtained for the higher functional levels are based on the data for the basic building block level.

Analysis Schedule

The analysis schedule lists the computations used in the analysis, the order in which they were performed, the input information needed by each computation, the assembly for which the computation was performed, and the

assemblies that need the information generated on this assembly in their calculations. Thus the first computation listed requires only input data. Subsequent computations may require input data plus the results of this first computation, etc. The analysis schedule provides a brief over-view of the entire analysis and can be used as a map to guide the reader through the analysis paths. The analysis schedule is presented only for the combined analysis since the schedule is the same for the other analyses.

Analysis Summary

The analysis summary provides the results of the analysis for the functional blocks of the system. Analysis summaries are provided for all functional blocks of the system utilizing the combined theoretical and flight test data. However, analysis summaries are provided only for the major functional blocks in the analyses based on theoretical and on flight-test data alone. The computer printout provides an explanation of the quantities given.

Summary of Results

The analysis summary described above includes a brief statement of the most important results of the analyses for each of the functional blocks. In this section the summary statement is listed for each of the functional blocks considered in the analysis. These summaries provide a complete listing of the results of the analyses of the Ka-band SATCOM Set.

Abbreviated Results

As noted above, analysis summaries based on the flight test data and the theoretical data are given for a few of the larger functional assemblies of the Ka-band System. These are given to provide a comparison among the analyses performed using the various data sources. As noted in the main body of this report, Battelle feels that the combined data analysis provides the best figures for most purposes.

3	.422200E-04	1.14716E+02	1.867	OTHER STATES
UNMIXED				

ASSEMBLY 203 OPERATES FOR 896,800 SECONDS TO COMPLETE ITS FUNCTION.
 THE AVAILABILITY IS .989314340, RELIABILITY IS .3978991536 AND DEPENDABILITY IS .9872359864.
 *15 MALFUNCTIONS ARE EXPECTED TO OCCUR DURING A MISSION CONSISTING OF 12 FUNCTIONAL CYCLES
 AND A DELAY OF 65.34 MINUTES IS EXPECTED WHEN A MALFUNCTION OCCURS.

ANALYSIS SUMMARY

FOR ASSEMBLY NUMBER 213

KA-BAND SAICOM SET (CONFERENCE CYCLE)

ASSEMBLY 213 IS USED BY ASSEMBLY(S) 201
